Gold: visible structure does not automatically predict the next move

1 Looking outside Kev: old extrema can drag a line after price has moved elsewhere

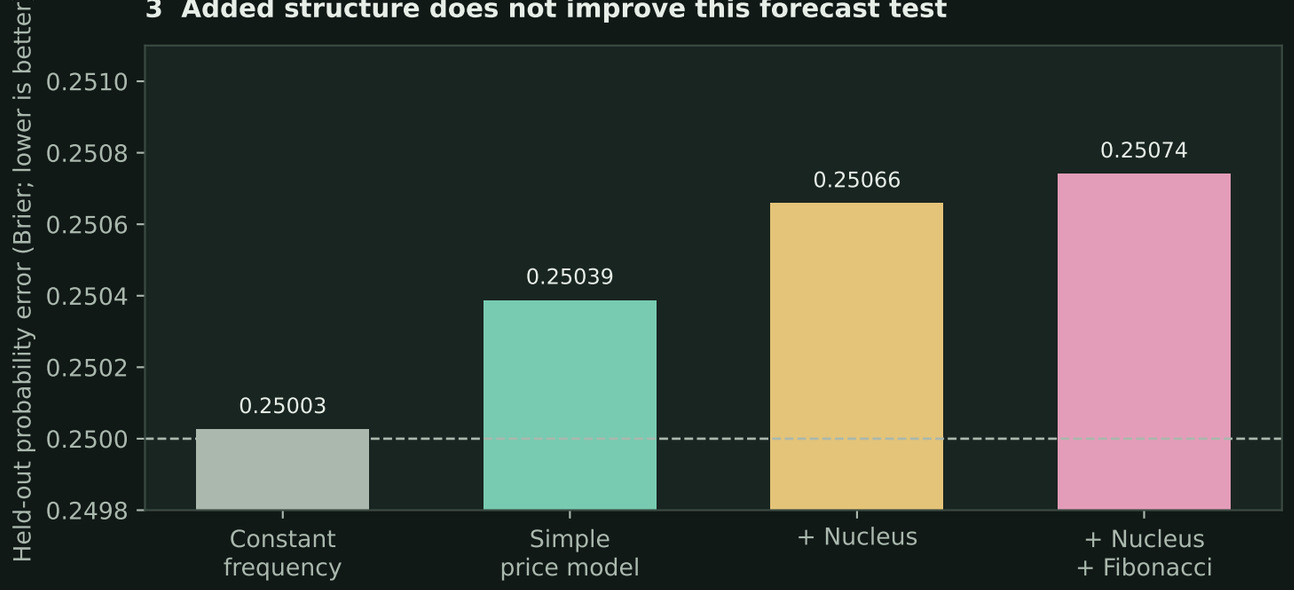

2 Fibonacci contacts do not stand out from nearby levels

First contact per level/week; next 8 contiguous M30 bars.
Matched displacement difference CI: −0.028 to +0.035 volatility units.

3 Added structure does not improve this forecast test

Fit through 2018; evaluate 2019–July 2026.
9,219 non-overlapping, gap-free four-hour target observations.

4 A structural lead: real gold is LESS synchronized

18 / 52 / 104 raw-M30 lookbacks; 99 paths per control.
Both corrected q = .03; nulls do not preserve all volatility dependence.

What we learned — and what remains unproven

MEMORY EXPIRY

A line can move because an old extreme disappears.
That is different from a new price impulse.

LEVEL DENSITY

76.1% of matched Fibonacci/control contacts share a bar.
Visual alignment alone is weak evidence.

STRUCTURAL DIFFERENCE

Cross-scale disagreement survives these two controls.
That is a research lead, not proof of emergence.

PREDICTION

No tested predictive increment passed the fixed rule.
This does not rule out every possible representation.
